

Title: METHOD FOR ELECTRONIC TUNING OF THE READ
OSCILLATION FREQUENCY OF A CORIOLIS GYRO

Inventor: Werner Schroeder

BACKGROUND

5 Field of the Invention

The present invention relates to Coriolis gyros. More particularly, this invention pertains to a method for electronic tuning of read oscillation frequency to stimulation oscillation frequency in such a device.

10 Description of the Prior Art

Coriolis gyros (also known as "vibration gyros") are increasingly employed for navigation. Such devices include a mass system that is caused to oscillate. Such oscillation is generally a superimposition of a large number
15 of individual oscillations. The individual oscillations of the mass system are initially independent of one another and each may be regarded in the abstract as a "resonator". At least two resonators are required for operation of a vibration gyro. A first resonator is artificially
20 stimulated to oscillate, with such oscillations referred to below as a "stimulation oscillation". A second resonator is stimulated to oscillate only when the vibration gyro is moved or rotated. That is, Coriolis forces occur which couple the first resonator to the second resonator, draw
25 energy from the stimulation oscillation of the first resonator, and transfer the energy to the read oscillation of the second resonator. The oscillation of the second resonator is referred to below as the "read oscillation". In order to determine movement (in particular rotation) of
30 the Coriolis gyro, the read oscillation is tapped off and a corresponding read signal (e.g. the tapped-off read oscillation signal) is analyzed to determine whether any

changes occurred in the amplitude of the read oscillation that measures rotation of the Coriolis gyro. Coriolis gyros may be in the form of either an open loop or a closed loop system. In a closed loop system, the amplitude of the read
5 oscillation is continuously reset to a fixed value (preferably zero) by control loops.

Figure 2 is a schematic diagram of a closed loop Coriolis gyro 1. The gyro 1 has a mass system 2 that can be caused to oscillate and is referred to below as a resonator
10 2 (in contrast to the "abstract" resonators, mentioned above, which represent individual oscillations of the "real" resonator). As already mentioned, the resonator 2 may be regarded as a system composed of two "resonators" (a first resonator 3 and a second resonator 4). Each of the first
15 and second resonators 3, 4 is coupled to a force transmitter (not shown) and to a tapping-off system (not shown). Noise produced by the force transmitter and the tapping-off system is indicated schematically by noise 1 (reference symbol 5) and noise 2 (reference symbol 6).

20 The Coriolis gyro 1 includes four control loops. A first control loop is employed for controlling the stimulation oscillation (i.e. the frequency of the first resonator 3) at a fixed frequency (resonant frequency). The first control loop has a first demodulator 7, a first low-
25 pass filter 8, a frequency regulator 9, a VCO (voltage controlled oscillator) 10 and a first modulator 11. A second control loop controls the stimulation oscillation at a constant amplitude and includes a second demodulator 12, a second low-pass filter 13 and an amplitude regulator 14.

30 Third and fourth control loops are used for resetting forces that stimulate the read oscillation. The third control loop includes a third demodulator 15, a third

low-pass filter 16, a quadrature regulator 17 and a second modulator 18. The fourth control loop comprises a fourth demodulator 19, a fourth low-pass filter 20, a rotation rate regulator 21 and a third modulator 22.

5 The first resonator 3 is stimulated at its resonant frequency ω_1 . The resultant stimulation oscillation is tapped off, demodulated in phase by means of the first demodulator 7, and a demodulated signal component passed to the first low-pass filter 8 that removes the sum
10 frequencies. The tapped-off signal is referred to below as the tapped-off stimulation oscillation signal. An output from the first low-pass filter 8 is supplied to a frequency regulator 9 that controls the VCO 10 as a function of the applied signal so that the in-phase component essentially
15 tends to zero. For this, the VCO 10 sends a signal to the first modulator 11, which controls a force transmitter so that a stimulation force is applied to the first resonator 3. When the in-phase component is zero, the first resonator 3 oscillates at its resonant frequency ω_1 . It should be
20 mentioned that all of the modulators and demodulators are operated on the basis of resonant frequency ω_1 .

 The tapped-off stimulation oscillation signal is also passed to the second control loop and demodulated by the second demodulator 12. The output of the second
25 demodulator 12 is passed through the second low-pass filter 13, whose output signal is, in turn, applied to the amplitude regulator 14. The amplitude regulator 14 controls the first modulator 11 as a function of such signal and of a nominal amplitude transmitter 23 such that the first
30 resonator 3 oscillates at a constant amplitude (i.e. the stimulation oscillation has constant amplitude).

As has already been mentioned, movement or rotation of the Coriolis gyro 1 results in Coriolis forces (indicated by the $FC \cdot \cos(\omega_1 \cdot t)$ in the drawing) that couple the first resonator 3 to the second resonator 4, causing the second resonator 4 to oscillate. A resultant read oscillation at frequency ω_2 is tapped off so that a corresponding tapped-off read oscillation signal (read signal) is supplied to both the third and fourth control loops. In the third control loop, this signal is demodulated by means of the third demodulator 15, the sum frequencies removed by the third low-pass filter 16, and the low-pass-filtered signal supplied to quadrature regulator 17 whose output is applied to the third modulator 22 so that corresponding quadrature components of the read oscillation are reset. Analogously, the tapped-off read oscillation signal is demodulated in the fourth control loop by means of a fourth demodulator 19. It then passes through a fourth low-pass filter 20 and the filtered signal is applied to a rotation rate regulator 21. The output of the rotation rate regulator 21 is proportional to the instantaneous rotation rate and is passed as the rotation rate measurement to a rotation rate output 24 and to the second modulator 18, which resets the corresponding rotation rate components of the read oscillation.

A Coriolis gyro 1 as described above can be operated in either a double-resonant form or in a form in which it is not double-resonant. When the Coriolis gyro 1 is operated in a double-resonant form, the frequency of ω_2 of the read oscillation is approximately equal to the frequency ω_1 of the stimulation oscillation. In contrast, when it is operated in a form in which it is not double-resonant, the frequency ω_2 of the read oscillation differs from the frequency ω_1 of the stimulation oscillation. In

the case of double-resonance, the output signal from the fourth low-pass filter 20 contains information about the rotation rate, while, when it is not operated in double-resonant form, the output signal from the third low-pass filter 16 contains the rotation rate information. A doubling switch 25 which selectively connects the outputs of the third and fourth low-pass filters 16, 20 to the rotation rate regulator 21 and to the quadrature regulator 17 is provided for switching between the double-resonant and non-double resonant modes.

When the Coriolis gyro 1 is operated in a double-resonant form, the frequency of the read oscillation is tuned, as mentioned, to that of the stimulation oscillation. This may be done to the resonator 2, for example by mechanical means, in which material is removed from the mass system. As an alternative, the frequency of the read oscillation can be set by means of an electrical field in which the resonator 2 is mounted to oscillate (i.e., by changing the electrical field strength). It is thus possible to tune the frequency of the read oscillation to the frequency of the stimulated oscillation electronically during operation of the Coriolis gyro 1.

SUMMARY AND OBJECTS OF THE INVENTION

It is an object of the invention to provide a method for electronically tuning the frequency of the read oscillation in a Coriolis gyro to that of the stimulation oscillation.

The invention addresses the preceding and other objects by providing, in a first aspect, a method for electronically tuning the frequency of the read oscillation in a Coriolis gyro. A disturbance force is applied to the resonator of the gyro so that the stimulation oscillation

remains essentially uninfluenced and the read oscillation is changed such that a read signal that represents the read oscillation contains a corresponding disturbance component. According to the method, the frequency of the read oscillation is controlled so that the magnitude of the disturbance component in the read signal is made as small as possible.

In a second aspect, the invention provides a Coriolis gyro having a rotation rate control loop and a quadrature control loop. Such gyro includes a device for electronic tuning of the frequency of the read oscillation to that of the stimulation oscillation.

Such device includes a disturbance unit that passes a disturbance signal to either the rotation rate control loop or to the quadrature control loop. A disturbance signal detection unit determines a disturbance component contained in a read signal produced by the disturbance signal. A central unit controls the frequency of the read oscillation so that the magnitude of the disturbance component contained in the read signal is as small as possible.

The preceding and other features of the invention will become further apparent from the detailed description that follows. Such description is accompanied by a set of drawings. Numerals of the drawings, corresponding to those of the written description, point to the features of the invention with like numerals referring to like features throughout.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a schematic diagram of a Coriolis gyro based on the method of the invention; and

Figure 2 is a schematic diagram of a Coriolis gyro in accordance with the prior art.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Figure 1 is a schematic diagram of a Coriolis gyro 1' based on the method of the invention. The Coriolis gyro 1' additionally includes a disturbance unit 26, a demodulation unit 27 and a read oscillation frequency regulator 28.

The disturbance unit 26 generates an alternating signal of frequency ω_{mod} that is added to the output of a quadrature regulator 21 (i.e. at the force output from the quadrature control loop). The collated signal obtained in this way is supplied to a (third) modulator 22 whose output is applied to a force transmitter (not shown), and, thus, to the resonator 2. As long as the frequency of the read oscillation does not essentially match that of the stimulation oscillation, the alternating signal produced by the disturbance modulation unit 26 is observed, after "passing through" the resonator 2, in the form of a disturbance component on the tapped-off read oscillation signal.

The tapped-off read oscillation signal is subjected to a demodulation process (carried out by means of a fourth demodulator 19) and supplied to a fourth low-pass filter 20 whose output is applied both to a rotation rate regulator 21 and to the demodulation unit 27. The signal supplied to the demodulation unit 27 is demodulated with a modulation frequency ω_{mod} that corresponds to the frequency of the alternating signal produced by the disturbance unit 26. The disturbance component (or the signal which represents the disturbance) is thus determined.

The demodulation unit 27 in this example can thus be regarded as a disturbance signal detection unit. An output signal from the demodulation unit 27 is supplied to the read oscillation frequency regulator 28 that sets the frequency of the read oscillation as a function of it so that the output signal from the demodulation unit 27 (i.e. the strength of the observed disturbance component) is a minimum. When a minimum has been reached, then the frequencies of the stimulation oscillation and the read oscillation essentially match. The signal supplied to the demodulation unit 27 may also, as an alternative to the signal supplied to the rotation rate regulator 21, be the signal that the rotation rate regulator 21 emits.

As mentioned above, and as an alternative, the alternating signal produced by the disturbance unit 26 can also be added to an output of the rotation rate regulator 21. In such case, the signal supplied to the demodulation unit 27 would be tapped off at the input or output of the quadrature regulator 17.

In principle, it is also possible to feed the disturbance signal (in this case the alternating signal, although other disturbance signals such as band-limited noise are also possible) into the quadrature control loop at any desired point (not only directly upstream of the third modulator 22, i.e., at any desired point between the point at which the read oscillation is tapped off and the third modulator 22). Analogous considerations apply to feeding the disturbance signal into the rotation rate control loop.

Once the Coriolis gyro 1' has been switched on, it is advantageous to set the modulation frequency ω_{mod} of the alternating signal to a high value to quickly achieve coarse control of the read oscillation frequency. It is then

possible to switch to a relatively low modulation frequency ω_{mod} to set resonance of the read oscillation precisely. Further, the amplitude of the modulation frequency ω_{mod} can be greatly reduced a certain amount of time after
5 stabilization of the rotation rate regulator 21 and/or of the quadrature regulator 17. Since the alternating signal at the output of the rotation rate control loop, (i.e. the third control loop) is compensated, there is generally no
10 need for any blocking filter for the modulation frequency ω_{mod} in the rotation rate control loop.

At the same time, the rotation rate regulator 21 associates the third demodulator 15 and the fourth demodulator 19 in phase with the force transmitters for the rotation rate control loop (cosine-wave forces) and the
15 quadrature control loop (sine-wave forces). The rotation rate (fourth control loop) and quadrature control loop (third control loop) can thus be separated even when phase shifts occur in the analog electronics of the Coriolis gyro 1'. These can occur, particularly as a function of
20 temperature. In general, a high bias will occur in the quadrature control loop. If this control loop and the rotation rate control loop are not clearly separated from one another, such bias will also appear in the rotation rate control loop.

25 Even when electronic frequency matching between the stimulation and the read oscillations is not desirable, the described control mechanism can be used to insure that the quadrature control loop and the rotation rate control loop are orthogonal. In this case, the controlled variable
30 is the reference phase of the third and fourth demodulators 15, 19, which are respectively "responsible" for quadrature components and rotation rate components of the read oscillation. This control process is preferably carried out

digitally in a signal processor (DSP) and renders the Coriolis gyro insensitive to phase shifts in the analog electronics.

5 In a second, alternative method for electronic
tuning the frequency of the read oscillation to that of the
stimulation oscillation in a Coriolis gyro, a disturbance
force is applied to the resonator of the Coriolis gyro so
that (a) the stimulation oscillation remains essentially
uninfluenced, and (b) the read oscillation is changed such
10 that a read signal which represents the read oscillation
contains a corresponding disturbance component. In this
way, the frequency of the read oscillation is controlled so
that any phase shift between a disturbance signal that
produces the disturbance force and the disturbance component
15 contained in the read signal is as small as possible. In
this case, "resonator" refers to the entire mass system (or
part of it) that can be caused to oscillate in the Coriolis
gyro (i.e., that part of the Coriolis gyro that is annotated
with reference numeral 2).

20 A significant discovery on which the second
alternative method is based is that the "time for
disturbance to pass through" the resonator (i.e., an
artificial change to the read oscillation resulting from the
application of appropriate disturbance forces to the
25 resonator), the time that passes from the effect of the
disturbance on the resonator until the disturbance is tapped
off as part of the read signal, is dependent on the
frequency of read oscillation. The shift between the phase
of the disturbance signal and the phase of the disturbance
30 component signal contained in the read signal is thus a
measure of the frequency of the read oscillation. It can be
shown that the phase shift assumes a minimum when the
frequency of the read oscillation essentially matches that

of the stimulation oscillation. If the frequency of the read oscillation is controlled such that the phase shift assumes a minimum, then the frequency of the read oscillation is at the same time essentially matched to the frequency of the stimulation oscillation.

In a third alternative embodiment of the method for electronic tuning of the frequency of the read oscillation to that of the stimulation oscillation in a Coriolis gyro, a disturbance force is applied to the resonator of the Coriolis gyro such that (a) the stimulation oscillation remains essentially uninfluenced and (b) the read oscillation is changed so that a read signal representing the read oscillation contains a corresponding disturbance component. The disturbance force is defined as the force caused by the signal noise in the read signal. The frequency of the read oscillation, in such case, is controlled so that the magnitude of the disturbance component contained in the read signal (i.e., the noise component) is as small as possible.

"Resonator" in this case refers to the entire mass system that can be caused to oscillate in the Coriolis gyro (i.e., that part of the Coriolis gyro which is identified by the reference number 2). The essential feature in this case is that the disturbance forces on the resonator change only the read oscillation, but not the stimulation oscillation. With reference to Figure 2, this would mean that the disturbance forces act only on the second resonator 4, but not the first resonator 3.

A significant discovery on which the third method is based is that a disturbance signal, in the form of signal noise, which occurs directly in the tapped-off read oscillation signal or at the input of the control loops

(rotation rate control loop/quadrature control loop), can be observed to a greater extent in the tapped-off read oscillation signal after "passing through" the control loops and the resonator, the less the frequency of the read oscillation matches the frequency of the stimulation oscillation. The signal noise (the signal noise of the read oscillation, tapping-off electronics or the random walk of the Coriolis gyro) is applied, after "passing through" the control loops, to the force transmitters and thus produces corresponding disturbance forces that are applied to the resonator and, thus, cause an artificial change in the read oscillation. The "penetration strength" of a disturbance such as this to the tapped-off read oscillation signal is thus a measure of how accurately the frequency of the read oscillation is matched to that of the stimulation oscillation. Thus, if the frequency of the read oscillation is controlled so that the penetration strength assumes a minimum, (i.e., the magnitude of the disturbance component which is contained in the tapped-off read oscillation signal, that is the noise component) then the frequency of the read oscillation is at the same time matched to the frequency of the stimulation oscillation.

The first method described for electronic tuning of the read oscillation frequency can be combined as required with the second method and/or with the third method. For example, it is possible to use the method described first while the Coriolis gyro is being started up (rapid transient response), and then to use the third method (slow control process) in steady-state operation.

A major discovery on which the invention is based is that an artificial change to the read oscillation in the rotation rate channel or quadrature channel is visible to a greater extent, in particular in the respective channel

which is orthogonal to it, the less the frequency of the read oscillation matches the frequency of the stimulation oscillation. The "penetration strength" of a disturbance such as this to the tapped-off read oscillation signal (in particular to the orthogonal channel) is thus a measure of how accurately the frequency of the read oscillation is matched to the frequency of the stimulation oscillation. Thus, if the frequency of the read oscillation is controlled so that the penetration strength assumes a minimum (i.e., such that the magnitude of the disturbance component which is contained in the tapped-off read oscillation signal is a minimum) then the frequency of the read oscillation is at the same time essentially matched to the frequency of the stimulation oscillation. The significant factor in this case is that the disturbance forces on the resonator change only the read oscillation, but not the stimulation oscillation. With reference to Figure 2, this means that the disturbance forces act only on the second resonator 4, but not on the first resonator 3.

The disturbance force is preferably produced by a disturbance signal that is supplied to appropriate force transmitters, or is added to signals which are supplied to the force transmitters. For example, a disturbance signal can be added to the respective control/reset signals for control/compensation of the read oscillation, to produce the disturbance force.

The disturbance signal is preferably an alternating signal (e.g. a superposition of sine-wave signals and cosine-wave signals). This disturbance signal is generally at a fixed disturbance frequency so that the disturbance component of the tapped-off read oscillation signal can be determined by means of an appropriate demodulation process carried out at the disturbance

frequency. One alternative is to use band-limited noise instead of an alternating signal. In this case, the disturbance component is demodulated from the read signal by correlation of the disturbance signal (noise signal) with the read signal (the signal which contains the disturbance component). The bandwidth of the noise in this case is dependent on the characteristics of the resonator 2 and of the control loops.

The method described above can be used for both an open loop and a closed loop Coriolis gyro. In the latter case, the disturbance signal is preferably added to the respective control/reset signals for control/compensation of the read oscillation. For example, the disturbance signal can be added to the output signal from a rotation rate control loop, and the disturbance component can be determined from a signal that is applied to or emitted from a quadrature regulator in a quadrature control loop. Conversely, the disturbance signal can be added to the output signal from the quadrature control loop, and the disturbance component can be determined from a signal that is applied to or is emitted from a rotation rate regulator in the rotation rate control loop. As an alternative, the disturbance signal can be added to the output signal from the quadrature control loop and the disturbance component determined from a signal which is applied to, or emitted from, a quadrature regulator in the quadrature control loop. It is also possible to add the disturbance signal to the output signal from the rotation rate control loop, and to determine the disturbance component from a signal which is applied to, or emitted from, a rotation rate regulator in the rotation rate control loop. The expression "read signal" covers all signals that are referred to in this paragraph and from which the disturbance component can be determined. In addition, the expression "read signal"

covers the tapped-off read oscillation signal.

The frequency of the read oscillation (i.e. the force transmission of the control forces which are required for frequency control) is in this case controlled by
5 controlling the intensity of an electrical field in which at least a part of the resonator oscillates, with an electrical attraction force. Such force, preferably non-linear, is established between the resonator and an opposing piece, fixed to the frame and surrounding.

10 While the invention has been described with reference to its presently-preferred embodiment, it is not limited thereto. Rather, the invention is limited only insofar as it is defined by the following set of patent claims and includes within its scope all equivalents
15 thereof.
